

# Autism Spectrum Disorders & ADHD: some conclusions from computational simulations

Włodzisław Duch & Co

Department of Informatics,  
Nicolaus Copernicus University, Toruń, Poland

Google: W. Duch

26<sup>th</sup> Marian Smoluchowski Symposium on Statistical Physics  
Complexity of Brain – Critical Behavior and Scaling, Kraków 28.31-.08.2013

# Plan:

- How can we understand neurodegenerative disease, such as autism, ADHD or epilepsy?
- Who is in the best position to do it?
- Observations: what do we know?
- Theories: do we understand it?
- Computational experiments.
- Mistaking symptoms for causes.
- Experimental evidence.
- Informed guesses, aka speculations

April is celebrated as the autism awareness month since 1970.

# Interdisciplinary Center of Innovative Technologies

Why am I interested in this?

Science without borders ...

Neurocognitive lab, including infant lab and many other projects, mostly experimental: fMRI + EEG, TMS, audiology, Cantab workstation etc ...

Still waiting for some equipment and furniture.

Understanding brain plasticity, development, mental states.

Funding >1M\$ for infant lab.

# A bit of ASD history

ASD: Autism Spectrum Disorder, includes many forms of autism.

Described for the first time in 1943 by Leo Kanner:

- “extreme aloneness from the beginning of life and anxiously obsessive desire for the preservation of sameness.”
- “... these children have come into the world with innate inability to form the usual, biologically provided affective contact with people ... ”.

Common deficit: lack of the theory of mind.

Initial theories:

- bad parents, refrigerator mothers ...
- a behavioral syndrome ... a developmental syndrome ...
- multiple disease entities, multiple etiologies, including metabolic and immune system deregulation, genetics.

2008: However, as in many areas of neuroscience, we are “data rich and theory poor” (Zimmerman, Autism – current theories).

# ASD

- Autism Spectrum of Disorders includes:
- Autism, Asperger syndrome, pervasive developmental disorder not otherwise specified (PDD-NOS), atypical forms of childhood disintegrative disorder, Rett syndrome, Infantile Autistic Bipolar Disorder (IABD), purine autism.
- 4-5 times more boys than girls.
- CDC estimates: average about 1%, boys about 2%.

## Autistic Savants:

few percent of people with ASD learn unusual memory or motor skills, but are impaired in many other ways.

# Autism Symptoms ...

Epidemics?

Not clear why: more attention, better diagnostics?

Very diverse, not a single disease, but more like dementia.

Genetic component, but search for “autism genes” not too successful, too many are involved.

Genetics cannot explain recent rapid increase.

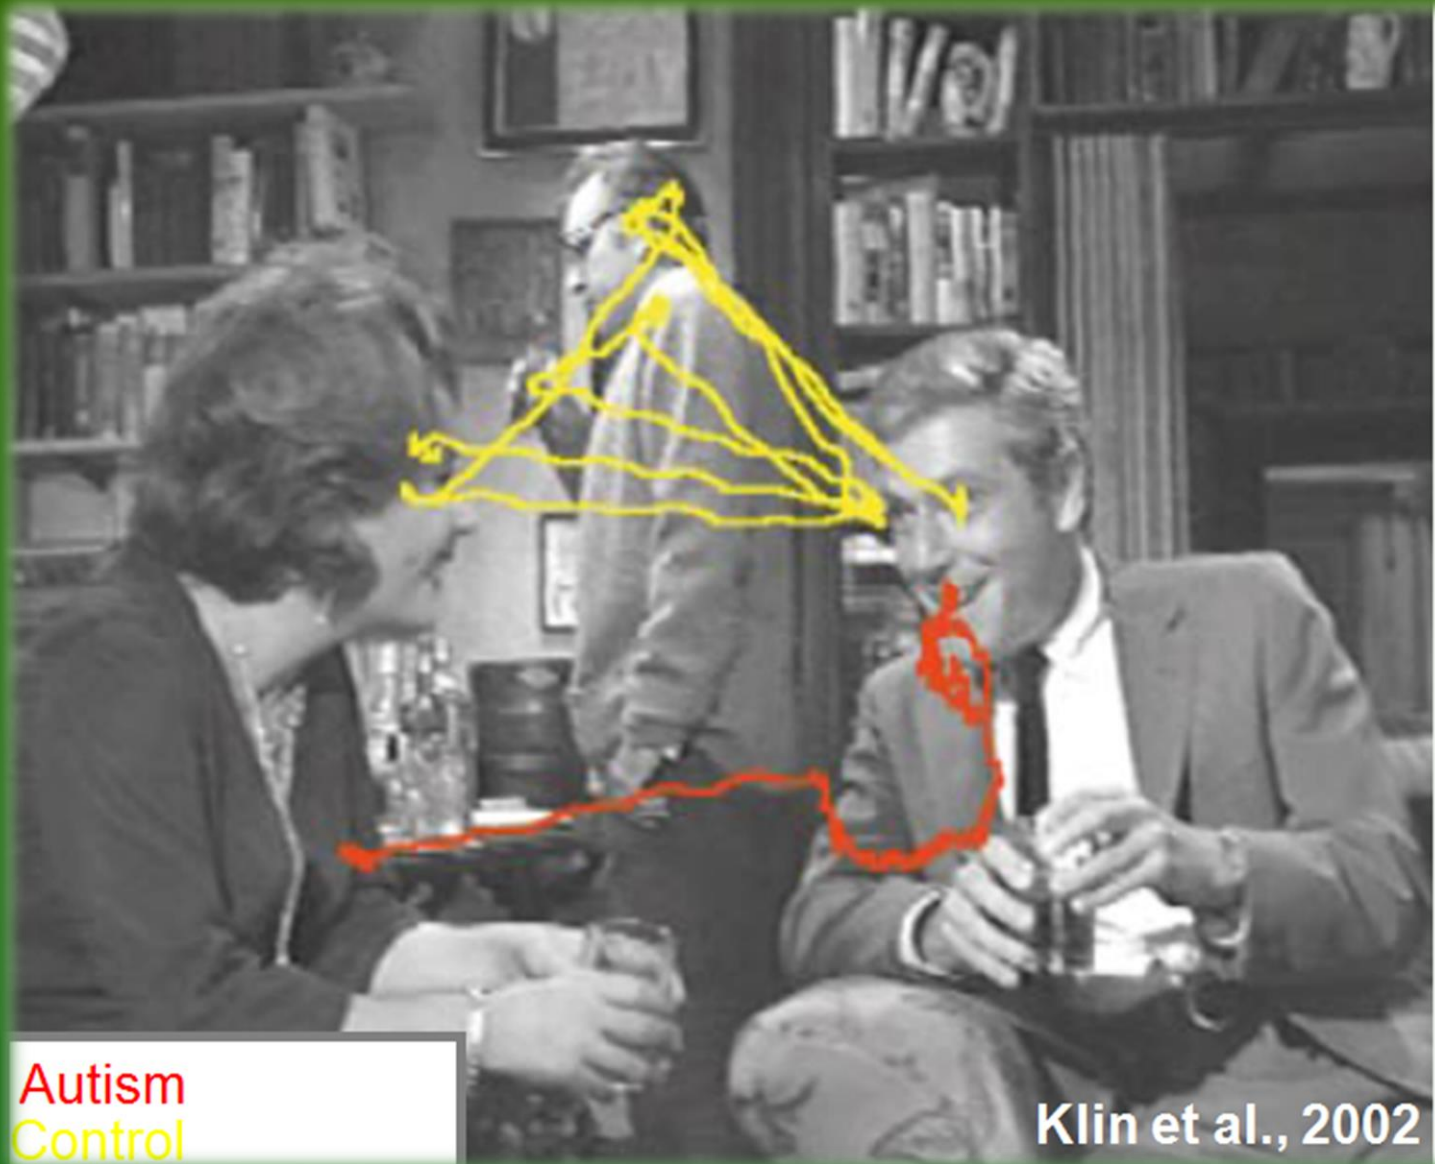

# ADHD

- Attention Deficit Hyperactivity Disorder, 3-5% of population (also adults).
- Problems with attention: usually impulsive-hyperactive, inattentive (ADD)
- Lack of impulse control, easily distracted, miss details, forget things, frequently switch between activity, can't focus on one thing ...
- Motor restlessness, run non-stop, lose things, are very impatient, display strong emotions, act without thinking about consequences.
- Bored quickly, daydream, difficulty in learning new things, complete homework.
- ADHD involves functional disconnections between frontal and occipital cortex (A. Mazaheri et al, Biological Psychiatry 67, 617, 2010); psychologist talk about deficit in "top-down" attention control.
- In many respects it is the opposite of ASD, but about 40% to 60% of people with ASD have also ADHD... see Duke University Center of Excellence (2017)

shapes. F. Castelli & et al. Brain 2002, 125 : 1839-49

Contrasting emotional vs. neutral conditions

# Theories, theories

Best book on ASD so far:

- Andrew W. Zimmerman (Ed.)  
Autism; current theories and evidence.  
Humana Press 2008.

20 chapters divided into six sections:

- Molecular and Clinical Genetics (4 chapters);
- Neurotransmitters and Cell Signaling (3 chapters);
- Endocrinology, Growth, and Metabolism (4 chapters);
- Immunology, Maternal-Fetal Effects, and Neuroinflammation (4 chapters);
- Neuroanatomy, Imaging, and **Neural Networks** (3 chapters);
- Environmental Mechanisms and Models (2 chapters).

Other: Grossberg ART model. At which level can we understand not just correlations, but real mechanisms responsible for behavioral symptoms?

(genes, proteins, biochemistry, ion channels, synapses, membranes)  
↔ (neural properties, networks) ↔ (behavior, syndromes, disease).

# Mirror Neuron System

- MNS: observing action elicits similar motor activations as if it had been performed by oneself; visuo-motor neurons.
- This helps to understand actions of others, modeling behavior via embodied simulation of their actions, intentions, and emotions.
- MNS theory of autism (Williams et al, 2001): distortion in the development of the MNS interferes with the ability to imitate, leads to social impairment and communication difficulties.
- Correlations between reduced MNS activity and severity of ASD are strong.

## Problems:

- In ASD abnormal brain activation is seen in many other circuits; performance of autistic children on various imitation tasks may be normal.
- MNS is used to explain almost everything in social neuroscience, but **MNS is not really a special subsystem, just multimodal neurons.**

# MNS EEG

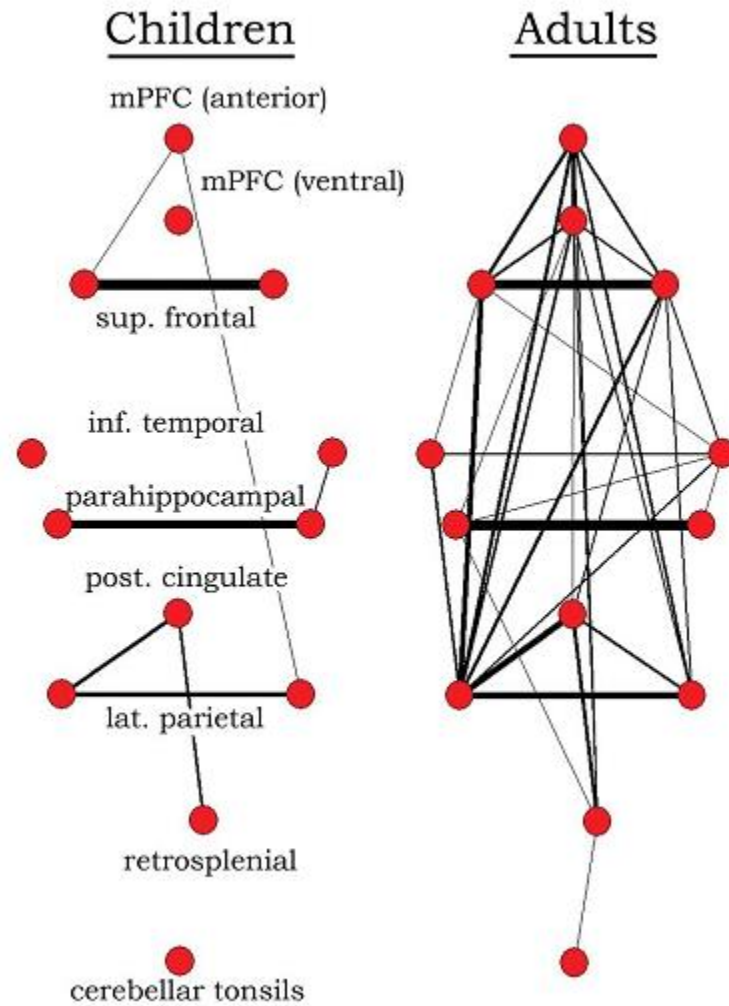

- EEG on controls and autistics on 4 different tasks, comparing mu rhythms. Baseline: large amplitude mu oscillations in synchrony. Seeing an action causes mu rhythms to fire asynchronously resulting in mu suppression.
- Mu wave suppression reflects activity of the mirror neuron system.
- In autistics mu is suppressed for own hand movements (Oberman 2005), but not for the observed hand movements of others (hand vs. move).

# Reduced fun

The underconnectivity theory

- Excess of low-level (sensorimotor) connectivity
- **Underfunctioning** of high-level (executive) connectivity
- fMRI and EEG study suggest overconnectivity in the connections between the frontal lobe and the rest of the brain
- **Underconnectivity** is mainly in the connections between the frontal lobe and the rest of the brain
- Patterns of low function are different depending on whether the individual is high or low functioning
- **“Default brain network”** (including the medial prefrontal cortex, mPFC, lateral PC), shows low activity for goal-related actions; it is active in social and emotional processing, mindwandering, daydreaming.
- Activity of the default network is negatively correlated with the “action network” (conscious goal-directed thinking), but this is not the case in autism – perhaps disturbance of self-referential thought?

ation,  
between  
and

ulate  
it is

# Functional connectivity

Model of autism is based on the following:  
(1) processes.

(2) Level neural connections and synchronization, suggests that adults with ASD have local connections and weak functional connections between distant parts of the cortex.

(3) High synchrony within each hemisphere of the cortex and that autism is a disorder of the association cortex.

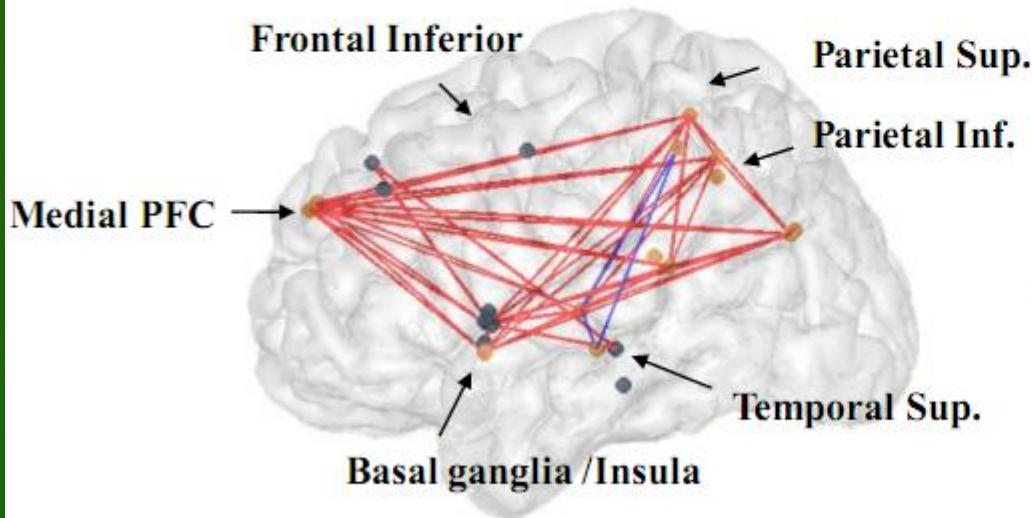

- Patterns of low function and aberrant activation in the brain differ depending on whether the brain is doing social or nonsocial tasks.
- “Default brain network” involves a large-scale brain network (cingulate cortex, mPFC, lateral PC), shows low activity for goal-related actions; it is active in social and emotional processing, mindwandering, daydreaming.
- Activity of the default network is negatively correlated with the “action network” (conscious goal-directed thinking), but this is not the case in autism – perhaps disturbance of self-referential thought?

Head position

Connectivity : 63 ROI analysis

— Significant in ASD not in Controls  
— Significant in Controls, not in ASD

● Region of the default mode network

● Region of the active network

Medial PFC

Brain activations in the FMRI experiment on emotion perception

# Effective brain connections

B. Wicker et al.  
SCAN 2008

# Executive dysfunction

- Hypothesis: autism results mainly from deficits in working memory, planning, inhibition, and other executive functions.
- Executive processes do not reach typical adult levels, resulting in stereotyped behavior and narrow interests.
- **But executive function deficits have not been found in young autistic children.**
- Weak central coherence theory hypothesizes that a limited ability to see the big picture underlies the central disturbance in autism.
- This predicts special talents in performance of autistic people.
- Enhanced perceptual functioning theory focuses more on the superiority of locally oriented and perceptual operations in autistic individuals.
- These theories agree with the underconnectivity theory of autism.
- **Social cognition theories poorly address autism's rigid and repetitive behaviors, while the nonsocial theories have difficulty explaining social impairment and communication difficulties.**

# Function connectivity theory

Model developed over 20 years (Nancy J. Minshew): autism as widespread disorder of association cortex, development of connectivity, only secondarily as a behavioral disorder. Fine, but still quite general.

Abnormalities in genetic code for brain development

Abnormal mechanisms of brain development

Structural and functional abnormalities of brain

Cognitive and neurologic abnormalities

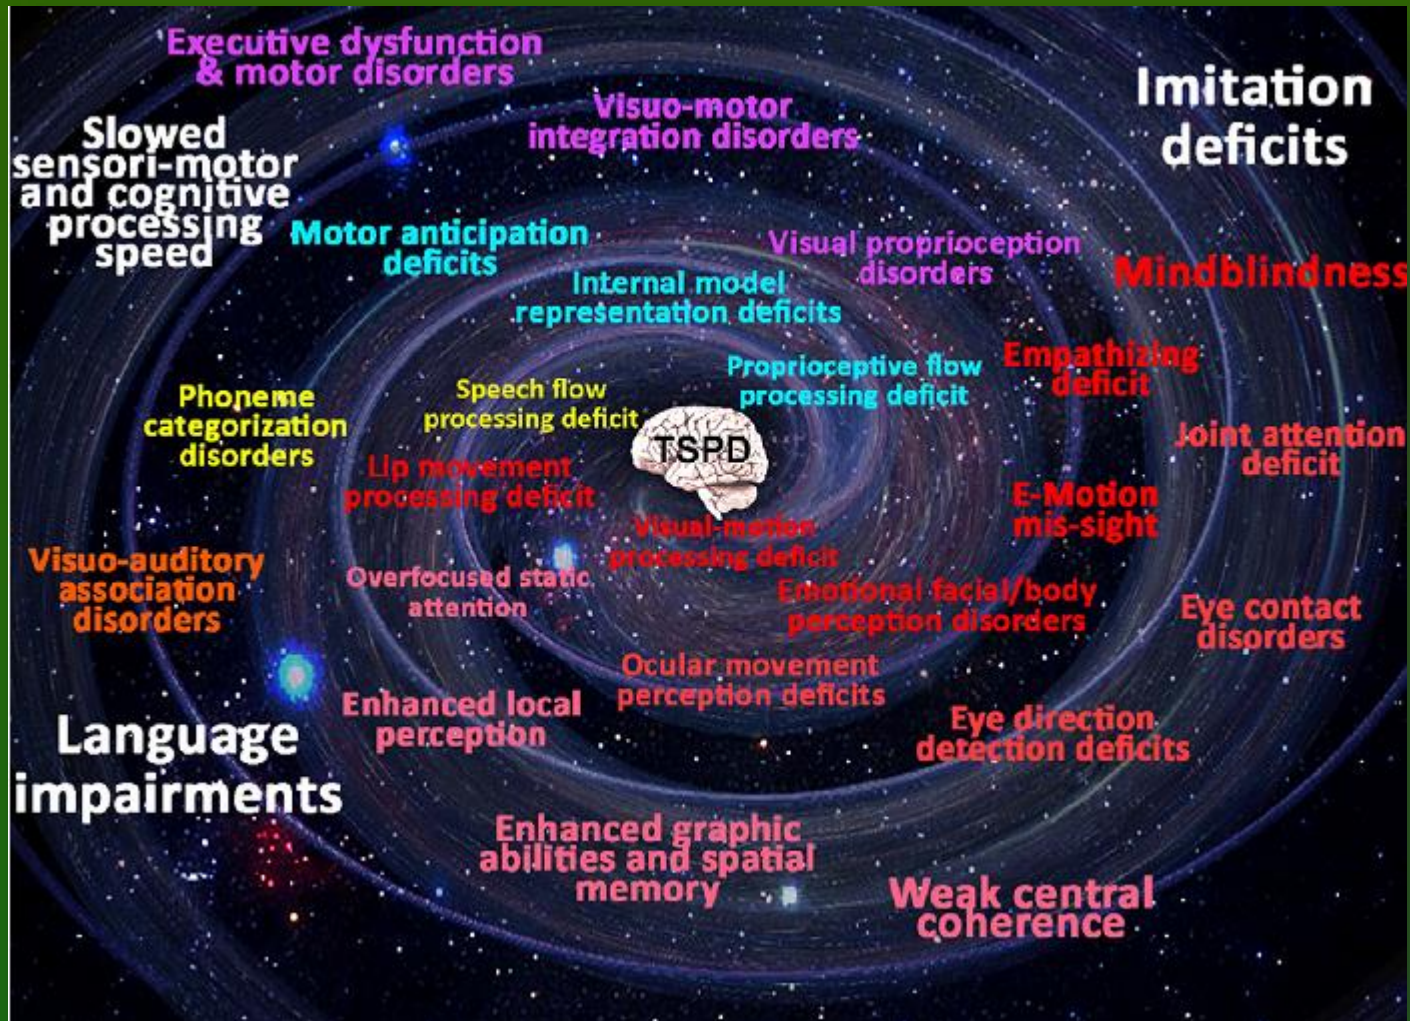

Behavioral syndrome

Goal: understand the pathophysiology from gene to behavior, eventually the influence of etiologies on this sequence, ultimately support the development of interventions at multiple levels of the pathophysiologic sequence.

# Temporo-spatial processing disorders

B. Gepner, F. Feron, Autism: A world changing too fast for a mis-wired brain? Neuroscience and Biobehavioral Reviews (2009).

# From Genes to Neurons

Genes => Proteins => receptors, ion channels, synapses  
=> **neuron properties, networks, neurodynamics**  
=> cognitive phenotypes, abnormal behavior, syndromes.

# From Neurons to Behavior

Genes => Proteins => receptors, ion channels, synapses  
=> neuron properties, networks  
=> **neurodynamics** => cognitive phenotypes, abnormal behavior!

# Neuropsychiatric Phenomics Levels

According to  
The Consortium for Neuropsychiatric  
Phenomics (CNP)

<http://www.phenomics.ucla.edu>

From genes to molecules to neurons and  
their systems to tasks, cognitive  
subsystems and syndromes.

Neurons and networks are right in the  
middle of this hierarchy.

# Neurocognitive Phenomics

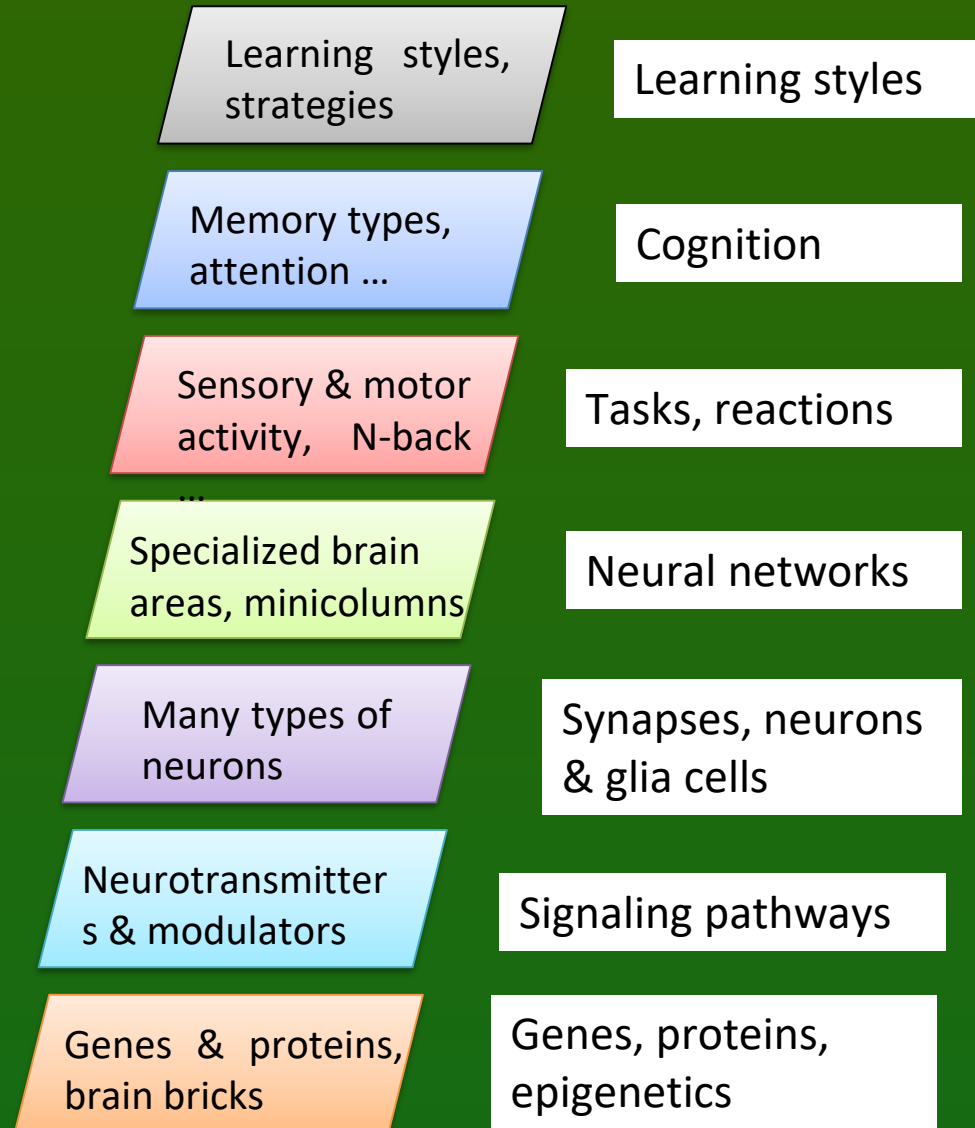

Phenotypes may be described on many levels, here from top down:

pedagogics,  
psychiatry,  
psychology,

neurophysiology,  
neural networks,

biology & neurobiology,  
biophysics & biochemistry,  
bioinformatics.

Neurocognitive phenomics is needed for development of learning sciences, but it is even greater challenge than neuropsychiatric phenomics, effects are more subtle.

# Neurophenomics Research Strategy

The Consortium for Neuropsychiatric Phenomics (2008):  
bridge all levels, one at a time, from environment to syndromes.

**Our strategy:** identify biophysical parameters of neurons required for normal neural network functions and leading to abnormal cognitive phenotypes, symptoms and syndromes.

- Start from simple neurons and networks, increase complexity.
- Create models of cognitive function that may reflect some of the symptoms of the disease, for example problems with attention.
- Test and calibrate the stability of these models in a normal mode.
- Determine model parameter ranges that lead to similar symptoms.
- Relate these parameters to the biophysical properties of neurons.

Result: mental events at the network level are described in the language of neurodynamics and related to low-level neural properties.

Example: relation of ASD/ADHD symptoms to neural accommodation.

# Research Group

Left to right: Darek Mikołajewski, Ewa Ratajczak, Krzysztof Dobosz, Grzegorz Markowski, Grzegorz Wójcik, Wiesław Nowak, Jarek Meller, Włodzisław Duch  
NCN (Polish National Science Foundation) Grant for pilot research.

# Computational Models

Models at various level of detail.

- Minimal model includes neurons with 3 types of ion channels.

Models of attention:

- Posner spatial attention;
- attention shift between visual objects.

Models of word associations:

- sequence of spontaneous thoughts.

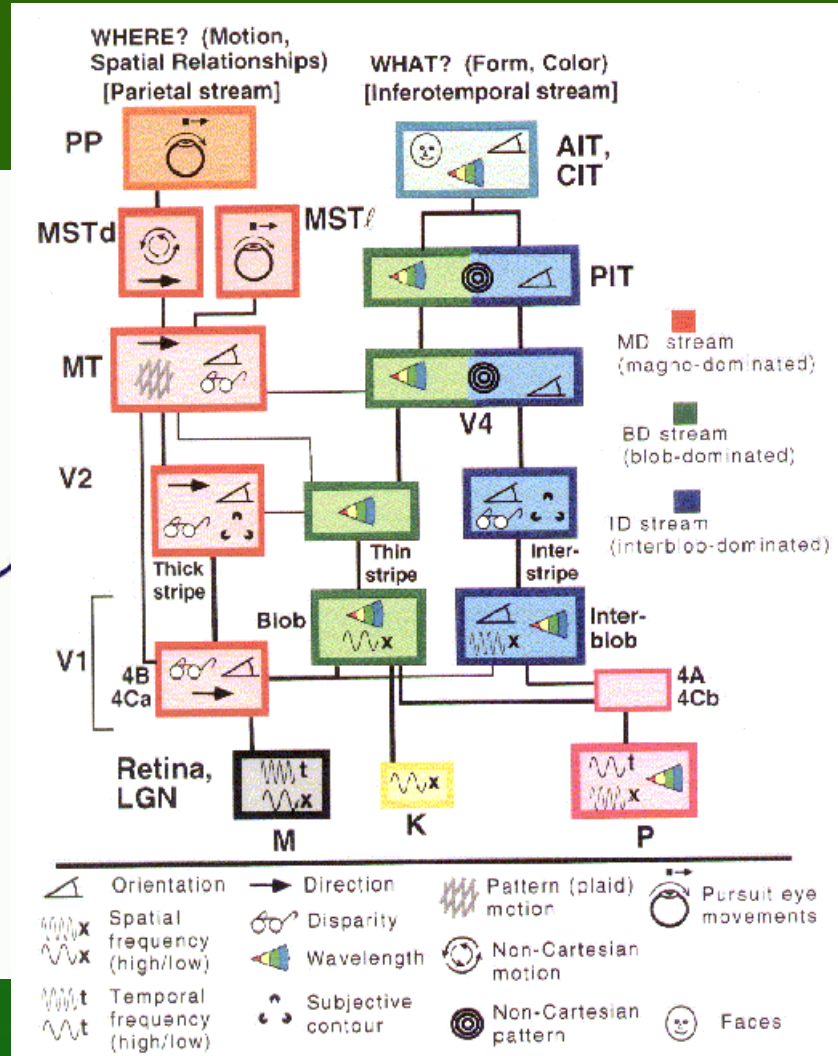

Models of motor control.

Critical: control of the increase in intracellular calcium, which builds up slowly as a function of activation. Initial focus on the leak channels, 2-pore  $K^+$ , looking for genes/proteins.

# Vision

From retina through lateral geniculate body, LGN (part of thalamus) information passes to the primary visual cortex V1 and then splits into the ventral and dorsal streams.

# Posner visual orientation task

Cue (bright box) is in the same position as target (**valid** trial), or in another position (**invalid** trial), or there is no cue (**neutral**), just target.  
Test of the object recognition/localization.

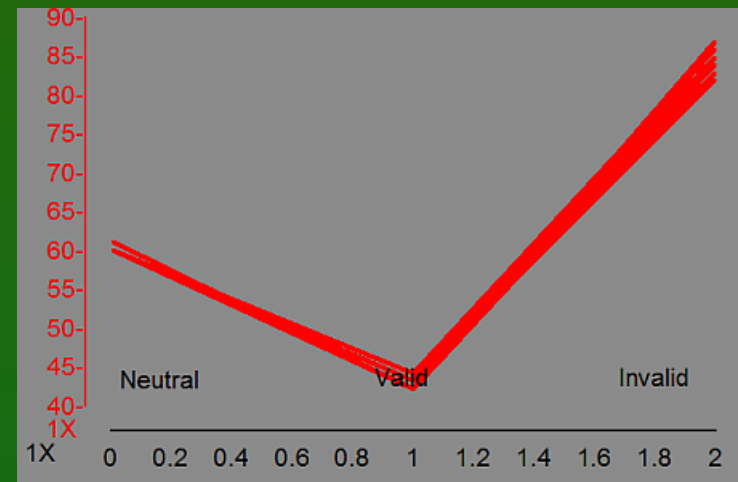

# Posner spatial attention

Cue (bright box) is in the same position as target (valid trial), or in another position (invalid trial), or there is no cue (neutral).

Group	Name	Input
Neutral	Target	
Valid	Cue	
Valid	Target	
Invalid	Cue	
Invalid	Target	

# Posner: Spat $\leftrightarrow$ Obj

Relative strength of the influence of spatial attention on object recognition (Spat $\Rightarrow$ Obj) reduced to zero makes neutral and valid trial times identical, but leaves the 20 ms difference between valid and invalid cases (top-down modulation effect).

Increase of this relative strength leads to slow increase of all reaction times, but the 20 ms differences are fairly stable between scaling from 1 to 5, with tendency to increase the invalid/neutral difference to 30 ms and slightly decrease of valid/neutral trials difference.

# Posner: V1=>Spat1

Decrease of relative strength of the influence of V1 layer on parietal spatial attention areas V1=>Spat1 leads to sharp increase in the invalid case, attention remains fixed for a longer time on the cue.

Decrease of this parameter from 2 to 1 increases the time difference between neutral and invalid trials ~3 times.

This may be one of the contributing factors to the problems with attention shifts in autism. While local circuits are well developed there is some evidence that distal connections are weak. Functional connections in autism have been linked to a variant of MET gene that shows high expression in the occipital cortex.

Judson M.C, Eagleson K.L, Levitt P.: A new synaptic player leading to autism risk: MET receptor tyrosine kinase. J. Neurodev. Disorders 3(3) (2011) 282–292

# Posner: recurrence in Spat

Relative strength of recurrent connections in Spat1 and Spat2 layers has no influence on valid trials, weak influence on neutral, but stronger local connections significantly increase reaction times of invalid trials.

This mechanism may also contribute to long delays in shifts of attention.

TSC gene can cause local over-connectivity in the sensory cortices (visual, auditory) reducing normal neuronal pruning.

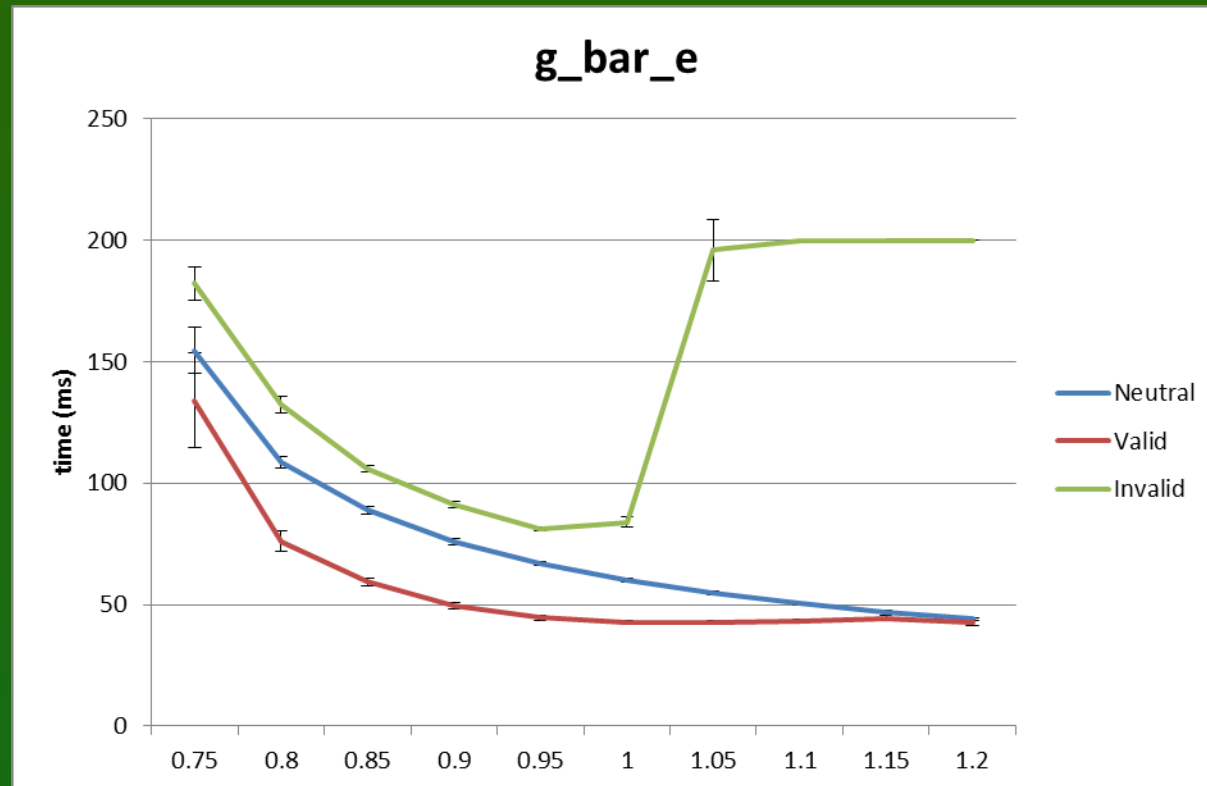

# Posner: excitation/inhibition

Increase of maximal conductance for excitatory channels (mostly glutamatergic synaptic sodium channels) above 1 leads to sharp two-fold increase in invalid trial reaction times, and small decrease of the normal/valid trials reaction times;

decrease of this parameter slows down reaction times but keeps the differences roughly constant.

Increasing maximal conductance for inhibitory channels quickly increases the invalid trials reaction times without much change in results for other trials;

decrease has relatively small effect.

# Posner: accomodation

Self-regulatory dynamics of neurons depends on complex processes, changing conductance of the ion channels (voltage-dependent gates).

Changing time constants for increases in intracellular calcium that builds up slowly as function of activation in all neurons has big influence on all reaction times, reducing the difference between all types of trials to zero and making reactions for valid trials slower than for invalid and neutral.

These processes depend on many types of ion channels and thus many genes are implicated.

# Posner: leak channels

Parameter regulating maximal conductance of leak (potassium  $K^+$ ) channels changed from 0.001 to 1.3 has relatively small influence on reaction times. Beyond this value all reaction times become much longer.

Strong leak currents decrease membrane potentials and activation of neurons takes longer time. The KCNK gene family proteins build two-pore-domain potassium leak channels, the main suspect in this case.

# Posner: noise

Noise may be included either as the variance of the value of membrane potential, or variance of the synaptic input.

The first type of noise makes the switch from invalid cue to the target position faster, decreasing sharply the time for invalid trials and to a smaller degree also other times.

Attractors become weaker and transitions may be made faster.

Synaptic noise has the opposite effect, competition between competing patterns becomes stronger and achieving the threshold for decision takes longer. High density of synapses will contribute to the “synaptic bombardment” type of noise.

# Posner spatial attention

- More complex cue = stronger local attractor => can bind ASD longer?
- Cue pulsating with different frequencies may create resonances?
- What changes in the network will lead to faster attention shifts?
- Broadening of attractor basins => helps to decrease symptoms?

- Diagnostic value?
- Explains fever effects?
- Suggest pharmacotherapy?
- Need for more accurate models.
- Model in GENESIS is inconclusive.

Spatial attention shifts in Posner experiments as a function of leak channel conductance change between 20-120 ms.

# Recognition of many objects

- Vision model including LGN, V1, V2, V4/IT, V5/MT

Two objects are presented.

Connectivity of these layers:

Spat1  $\Leftrightarrow$  V2, Spat 2

Spat1  $\Leftrightarrow$  V2, Spat 2

Spat2  $\Leftrightarrow$  V2.

Spat1 has recurrent activations and inhibition, focusing on a single object.

In normal situations neurons desynchronize and synchronize on the second object = attention shift.

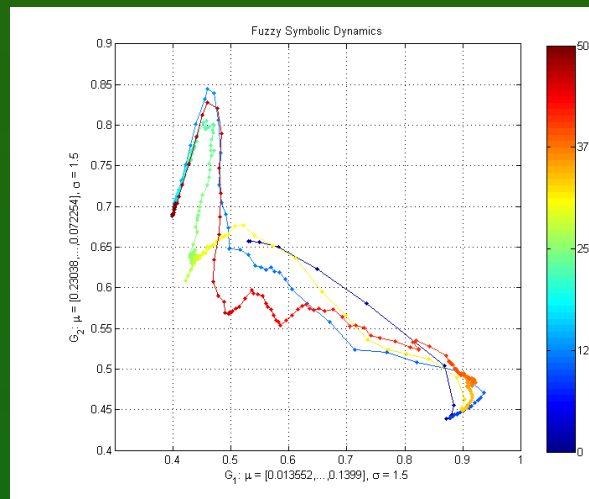

# Model of movements

Model of cyclic movements was constructed using several simple patterns representing the movement of left and right arm, hand, leg, foot, reflected as a sequence of activations in the input layer with addition of the accommodation mechanism (i.e. neural fatigue). Output layer represents activations within the motor cortex (left arm).

“Sliding attractors” are sometimes followed by irregular movements, ex. in speech, singing, gestures etc.

# Model of reading

## Spontaneous transitions.

Emergent neural simulator:

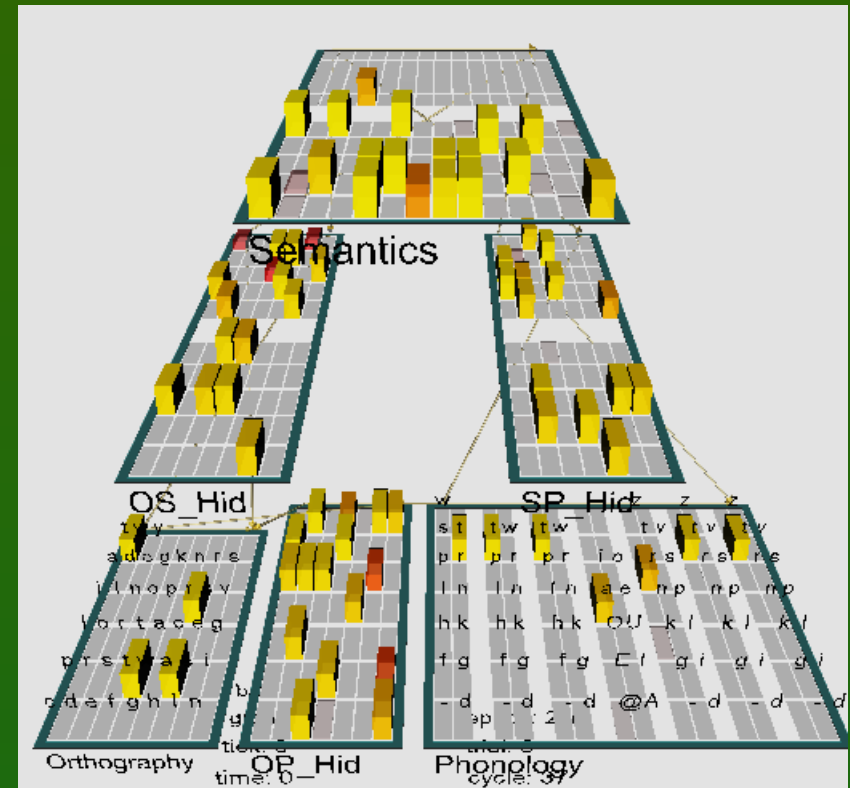

Aisa, B., Mingus, B., and O'Reilly, R.

The emergent neural modeling system. Neural Networks, 2008.

3-layer model of reading:

orthography, phonology, semantics,  
or distribution of activity over 140  
microfeatures of concepts.

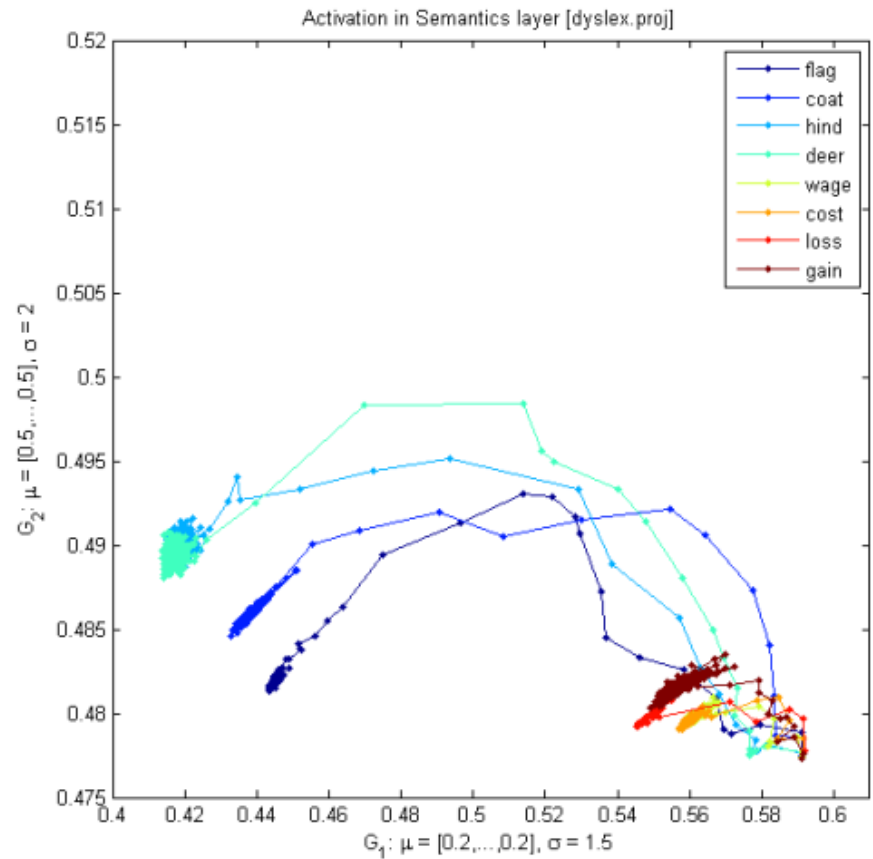

Hidden layers in between.

Learning: mapping one of the 3 layers to the other two.

Fluctuations around final configuration = attractors representing concepts.

How to analyze properties of attractor basins, their relations?

standardized data and optimize t  
of trajectories despite reduced d

$$y_k(t; \boldsymbol{\mu}_k, \Sigma_k) = \exp\left(-\left(x(t) - \boldsymbol{\mu}_k\right)^T \Sigma_k^{-1} \left(x(t) - \boldsymbol{\mu}_k\right)\right)$$

This creates localized membership functions  $y_k(t; W)$ .

Sharp indicator functions => symbolic dynamics;  $x(t)$  => strings of symbols.

Soft membership functions => fuzzy symbolic dynamics, dimensionality reduction  $Y(t) = (y_1(t; W), y_2(t; W))$  => visualization of high-D data.

- Dobosz K, Duch W, Neural Networks 23, 487-496, 2010;  
Cognitive Neurodynamics 5(2), 145-160, 2011

# Attractors for words

Model for reading includes phonological, orthographic and semantic layers with hidden layers in between.

FSD/RP visualization of activity of the semantic layer with 140 units.

*Cost* and *rent* have semantic associations, attractors are close to each other, but without noise or accommodation transitions between basins of attractions are hard.

Will these relations show up in verbal priming tests? Free associations?

Will broadening of phonological/written form representations help?

For example, will training ASD children with characters that vary in many ways (shapes, colors, size, rotations) help them to form broader categories?

# Neurodynamics

Trajectories show spontaneous attention shifts that emerge as a property of neurodynamics, and depends on:

- **synaptic connections**: local connectivity, inhibitory competition, bidirectional inter/intralayer processing, multiple constraint satisfaction ...
- **neural properties**: thresholds, accommodation, exc/inh/leak conductance ...

Input activations: transients => basins of attractors => object recognition

- Normal case: relatively large basins, generalization, average dwell time, moving to other basin of attraction, exploring the activation space.
- Without accommodation (inactive outward rectifying ion channels): deep, narrow basins, hard to move out of the basin, associations are weak.

Accommodation: basins of **attractors shrink and vanish** because neurons desynchronize due to the neural fatigue. This allows other neurons to synchronize on new stimuli, guided by Spat => V2 => V1 feedback.

This leads to sudden spontaneous weakly related chains of thoughts.

# Recurrence plots

Starting from the word “flag”, with small synaptic noise ( $\text{var}=0.02$ ), the network starts from reaching an attractor and moves to another one (frequently quite distant), creating a “chain of thoughts”.

Same trajectories displayed with recurrence plots, showing roughly 5 larger basins of attractors and some transient points.

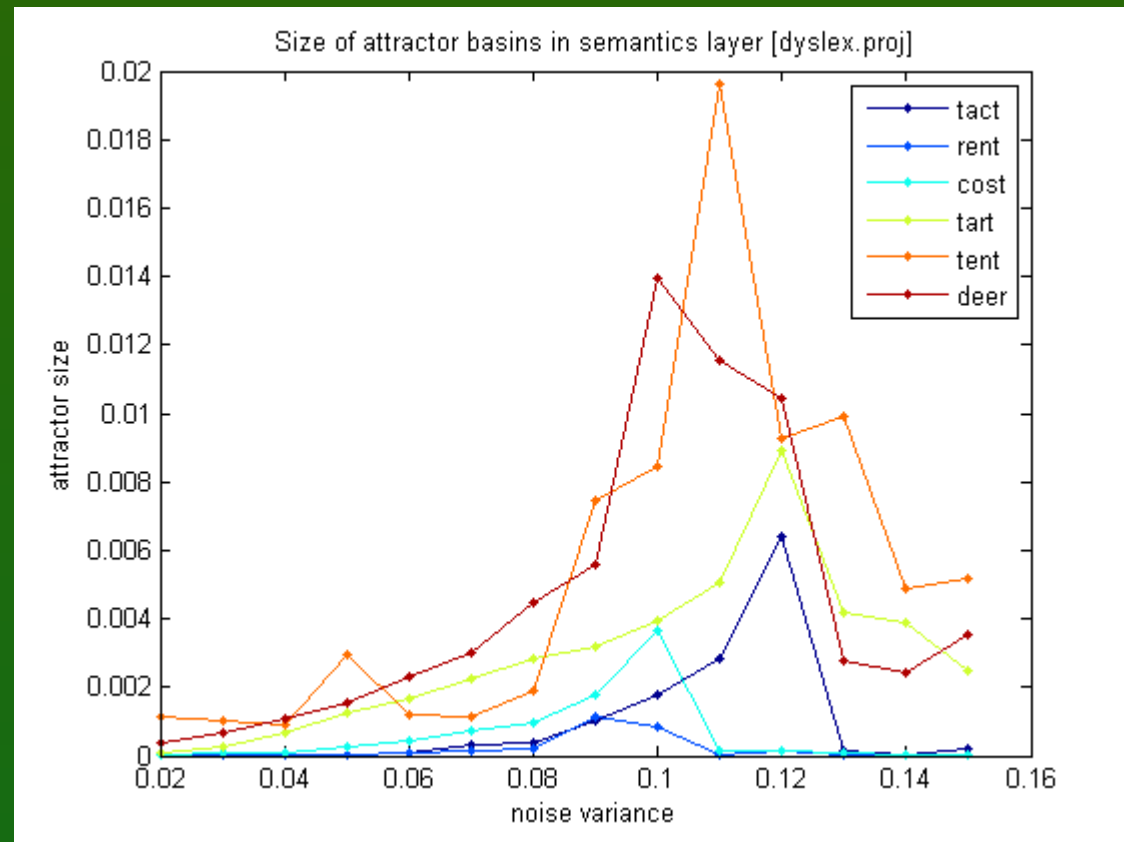

# How strong are attractors?

Variance around the center of a cluster grows with synaptic noise; for narrow and deep attractors it will grow slowly, for wide basins it will grow fast.

Jumping out of the attractor basin reduces the variance due to inhibition of desynchronized neurons.

More varied encoding of concrete nouns seems to help creating larger attractor basins.

Abstract concepts show narrow and deep basins, variance is small and suddenly increases.

# Probability of recurrence

Probability of recurrence may be computed from recurrence plots, or from clusterization of trajectory points, allowing for evaluation how strongly some basins of attractors capture neurodynamics.

[Our Viser Toolbox](#) is used for all visualizations

# Fast transitions

Attention is focused only for a brief time and then moved to the next attractor basin, some basins are visited for such a short time that no action may follow, no chance for other neuronal groups to synchronize. This corresponds to the feeling of confusion, not being conscious of fleeting thoughts.

# Normal-Autism

All plots for the flag word, different values of  $b\_inc\_dt$  parameter in the accommodation mechanism.  $b\_inc\_dt = 0.01$  &  $b\_inc\_dt = 0.005$   
 $b\_inc\_dt$  = time constant for increases in intracellular calcium building up slowly as a function of activation, controls voltage-dependent leak channels.

<http://kdobosz.wikidot.com/dyslexia-accommodation-parameters>

# Normal-ADHD

All plots for the flag word, different values of  $b\_inc\_dt$  parameter in the accommodation mechanism.  $b\_inc\_dt = 0.01$  &  $b\_inc\_dt = 0.02$

$b\_inc\_dt$  = time constant for increases in intracellular calcium which builds up slowly as a function of activation.

<http://kdobosz.wikidot.com/dyslexia-accommodation-parameters>

# Inhibition

Increasing  $g_i$  from 0.9 to 1.1 reduces the attractor basin sizes and simplifies trajectories.

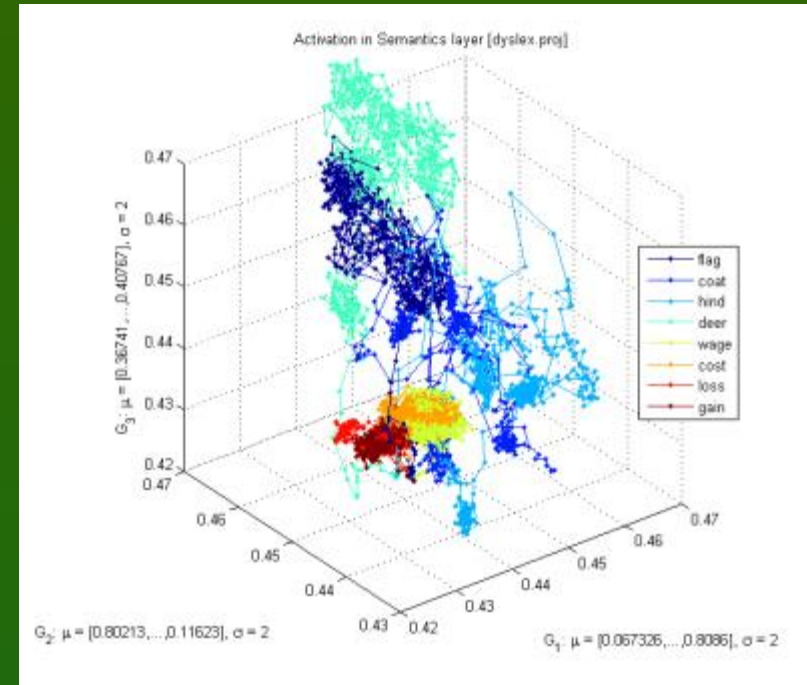

Strong inhibition, empty head ...

# Connectivity: strong recurrence

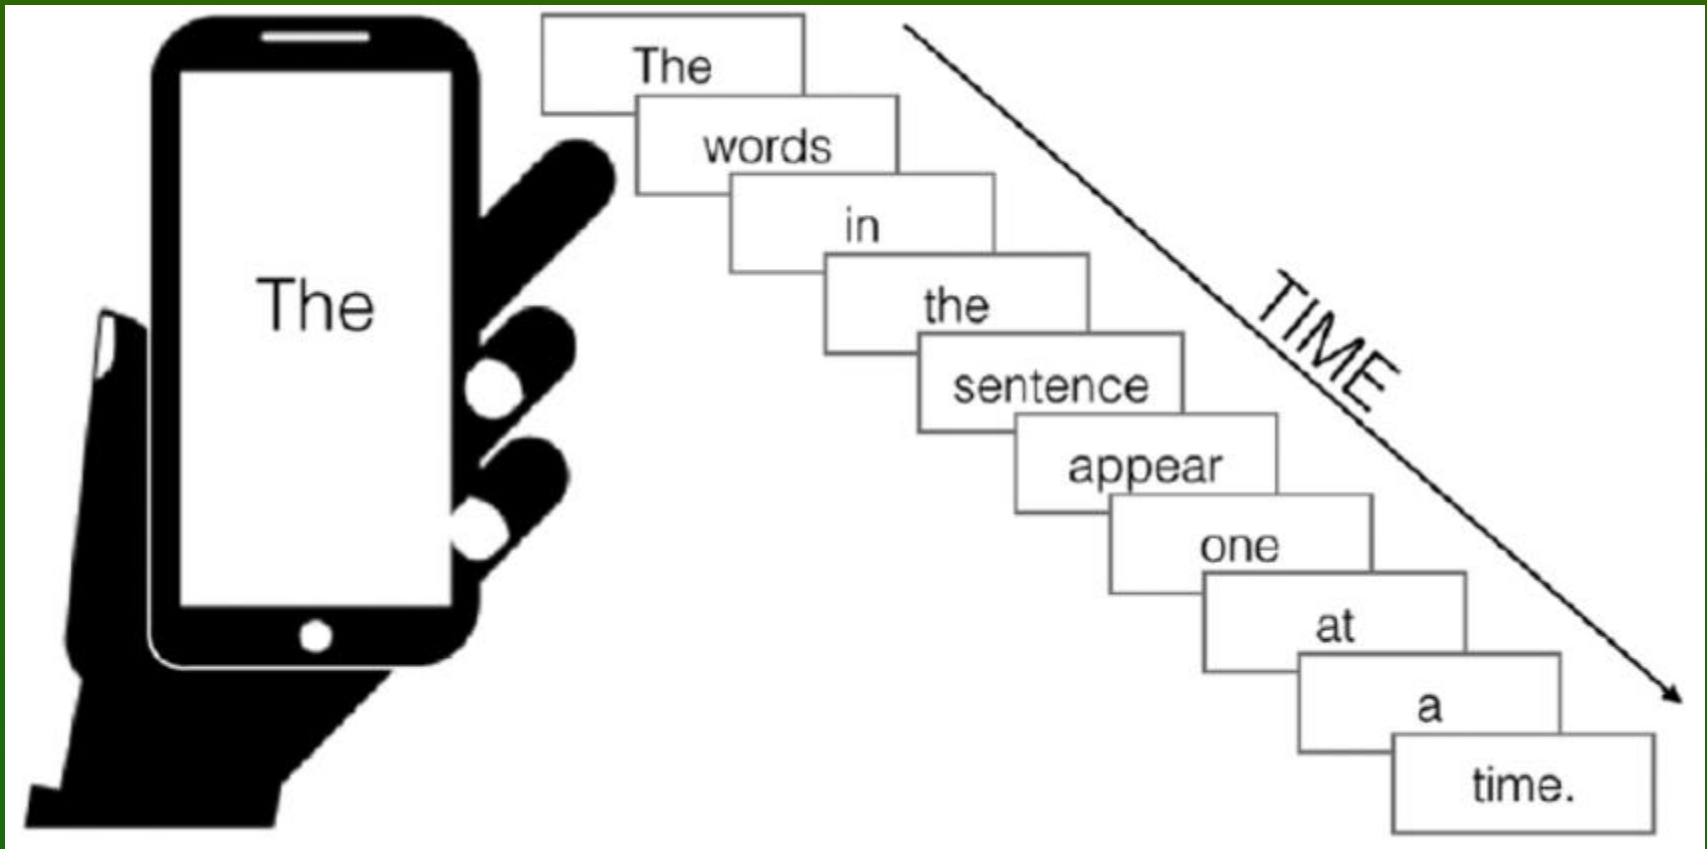

With small synaptic noise (var=0.02) the network starts from reaching an attractor and moves to another one (frequently quite distant), creating a “chain of thoughts”.

Same situation, with stronger recurrent connections within layers; fewer but larger attractor basins are created, and more time is spent in each basin.

# Rapid Serial Visual Presentation

Simulation: showing series of words, looking for attention/associations.  
star => flea => tent => lock => tart => hind

# RSVP simulations: normal

Typical case: accommodation  
 $b\_inc\_dt = 0.01$ , normal presentation  
500 it/word

$b\_inc\_dt = 0.01$ , fast presentation  
100 it/word

# RSVP simulations:HFA

High functioning ASD case (HFA): accommodation

$b\_inc\_dt = 0.005$ , normal presentation

500 it/word

$b\_inc\_dt = 0.005$ , fast presentation

100 it/word

# RSVP simulations: ASD

Severe ASD case: accommodation  
 $b\_inc\_dt = 0.001$ , normal presentation  
500 it/word

$b\_inc\_dt = 0.001$ , fast presentation  
100 it/word

# Some speculations

Attention shifts may be impaired due to several factors:

1. Deep and narrow attractors that entrap dynamics – due to leak channels?

Explains overspecific memory in ASD, unusual attention to details, the inability to generalize visual and other stimuli but not olfactory.

2. Shallow and broad attractors:  
ADHD short attention span, need for psychostimulants to stabilize ADHD.
3. Accommodation: voltage-dependent  $K^+$  channels (~40 types) do not decrease depolarization in a normal way, attractors do not shrink.

This effect should also slow down attention shifts and reduce jumps to unrelated thoughts or topics relative to average person – neural fatigue will temporarily switch them off preventing activation of attractors that code significantly overlapping concepts.

What behavioral changes are expected? How to test it?

# Learning connectome styles

Simple connectome models may help to connect and improve learning classification of the styles.

S, Sensory level, occipital, STS, and somatosensory cortex;

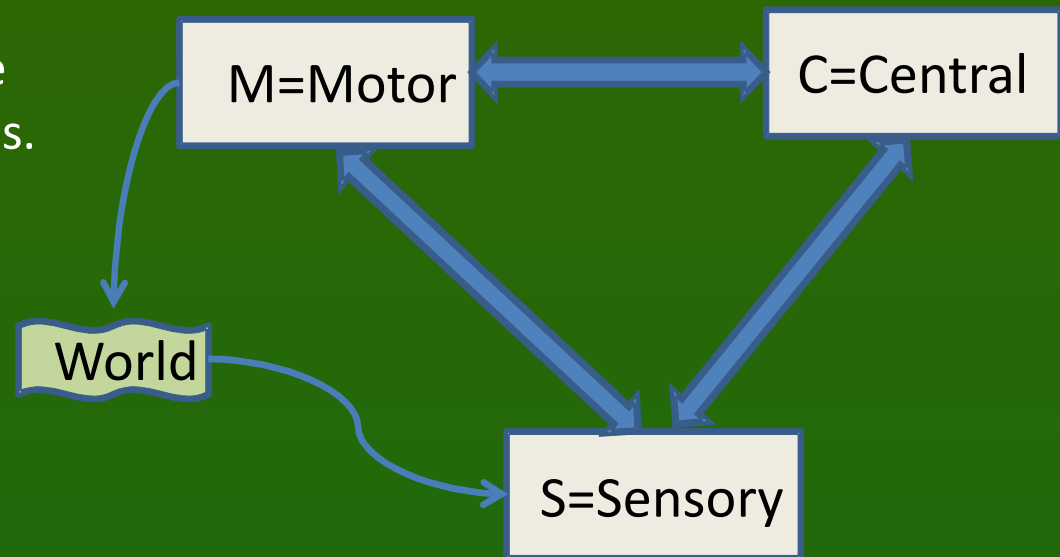

C, central associative level, abstract concepts that have no sensory components,

mostly parietal, temporal and prefrontal lobes;

M, motor cortex, motor imagery & physical action. Frontal cortex, basal ganglia.

Even without emotion and reward system predominance of activity within or between these areas explains many learning phenomena.

**Look-up table algorithms:** Qian N, Lipkin RM. A learning-style theory for understanding autistic behaviors. *Frontiers of Human Neuroscience* 2011.

# Learning styles 1<sup>st</sup> D

Kolb perception-abstraction:  
coupling within sensory  $S \leftrightarrow S$  areas,  
vs. coupling within central  $C \leftrightarrow C$  areas.

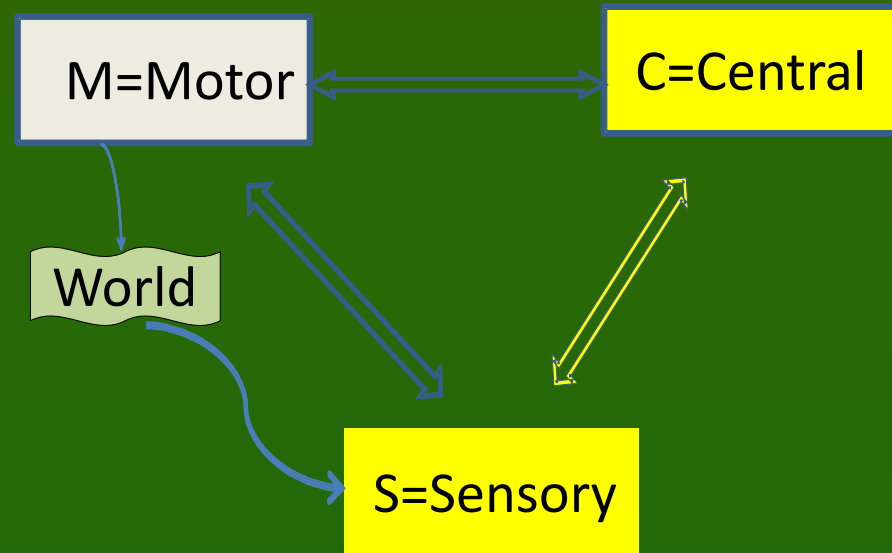

Strong  $C \Rightarrow S$  leads to vivid imagery  
dominated by sensory experience.

Autism: vivid detailed imagery,  
no generalization. Cows will panic if they  
enter barn ... (Temple Grandin).

Attention = synchronization of neurons, limited to  $S$ , perception  $S \leftrightarrow S$  strongly  
binds attention, no chance for normal development.

Asperger syndrome strong  $C \Rightarrow S$  activates sensory cortices preventing  
understanding of metaphoric language.

If central  $C \leftrightarrow C$  processes dominate, no vivid imagery but efficient abstract  
thinking is expected: mathematicians, logicians, theoretical physicist,  
theologians and philosophers ideas.

# Geometric model of mind

Objective  $\Leftrightarrow$  Subjective.

Brain  $\Leftrightarrow$  Mind.

Neurodynamics describes state of the brain activation measured using EEG, MEG, NIRS-OT, PET, fMRI or other techniques.

How to represent mind state?

In the space based on dimensions that have subjective interpretation: intentions, emotions, qualia.

Mind state and brain state trajectory should then be linked together by transformations (BCI).

Need for neurophenomenology.

# Research/diagnostic consequences

Many problems at genetic/molecular level may lead to the same behavioral symptoms => problems for statistically-oriented research methods.

- Genetic mutation should give weak signals: in a given population of autistic patients only small fraction will have a given mutation.
- Inconclusive results on diet: several studies show some improvement, other studies show no effect.
- Pharmacological and other treatments will have limited success.
- Need for a better diagnostics at molecular/genetic level!

Strategy: behavior  $\leq$  neural properties;

- find neural parameters that affect behavior in a specific way;
- try to relate them to molecular properties in synapses, various receptors, ion channels (pore forming proteins), membrane properties;
- try to find markers for specific abnormalities.

# Behavioral consequences

Deep, localized attractors are formed; what are the consequences?

- Problems with disengagement of attention;
- hyperspecific memory for images, words, numbers, facts, movements;
- strong focus on single stimulus, absorption, easy sensory overstimulation;
- gaze focused on simple stimuli, not faces, contact is difficult;
- echolalia, repeating words without understanding (no associations); nouns are acquired more readily than abstract words like verbs;
- play is schematic, fast changes are not noticed (stable states cannot arise);
- play with other children is avoided in favor of simple toys;
- generalization and associations are quite poor; integration of different modalities that requires synchronization is impaired, connections are weak;
- normal development – theory of mind, MNS, relations – is impaired.

**Simple basic deficit => host of problems**, many insights from such mechanisms. Expect great diversity of symptoms, depending on local expression and severity.

# Slower processing – deep attractors

Hypothesis: deep attractors => longer trapping times => slower processing => lack of internal stimulations => underconnectivity.

Hedvall, Å., Fernell, E., Holm, A., Åsberg Johnels, J., Gillberg, C., & Billstedt, E. (2013). Autism, Processing Speed, and Adaptive Functioning in Preschool Children. *The Scientific World Journal* 2013, ID 158263

Haigh, S. M., Walsh, J. A., Mazefsky, C. A., Minshew, N. J., & Eack, S. M. (2018). Processing Speed is Impaired in Adults with Autism Spectrum Disorder, and Relates to Social Communication Abilities. *Journal of Autism and Developmental Disorders*. Epub ahead of print.

Good measure of brain processing speeds?

Wechsler Preschool and Primary Scale of Intelligence-III subtests “Coding and Symbol Search” comprise the processing speed quotients (PSQs).

Subtests on the MATRICS Consensus Cognitive Battery.

# Experimental evidence: behavior

Kawakubo Y, et al. Electrophysiological abnormalities of spatial attention in adults with autism during the gap overlap task. *Clinical Neurophysiology* 118(7), 1464-1471, 2007.

- “These results demonstrate electrophysiological abnormalities of disengagement during visuospatial attention in adults with autism which cannot be attributed to their IQs.”
- “We suggest that adults with autism have deficits in attentional disengagement and the physiological substrates underlying deficits in autism and mental retardation are different.”

Landry R, Bryson SE, Impaired disengagement of attention in young children with autism. *Journal of Child Psychology and Psychiatry* 45(6), 1115 - 1122, 2004

- “Children with autism had marked difficulty in disengaging attention. Indeed, on 20% of trials they remained fixated on the first of two competing stimuli for the entire 8-second trial duration.”

Several newer studies: [Mayada Elsabbagh](#).

# Experimental evidence: behavior

D.P. Kennedy, E. Redcay,  
and E. Courchesne,

Failing to deactivate:  
Resting functional abnor-  
malities in autism. PNAS  
103, 8275-8280, 2006.

Default network in autism  
group failed to deactivate  
brain regions, strong  
correlation between a  
clinical measure of social  
impairment and function-  
al activity within the  
ventral MPF.

Mistaking symptoms for real problems:

We speculate that the lack of deactivation in the autism group is indicative of abnormal internally directed processes at rest.

# Mistaking symptoms for causes

Various brain subsystems develop in an abnormal way:

1. **Abnormal functional connectivity** between extra striate and temporal cortices during attribution of mental states, and executive tasks such as memory for or attention to social information (Castelli et al., 2002 ; Just et al., 2004, 2007; Kana et al., 2007a, b; Dichter et al., 2007; Kleinhans et al., 2008).

2. **Underconnectivity**: working memory, face processing (Just et al., 2007; Koshino et al., 2008; Bird et al., 2006), cortico-cortical connectivity (Barnea-Goraly et al., 2004; Herbert et al., 2004; Keller et al., 2007).

3. **Default mode network**: “Results revealed that while typically developing individuals showed enhanced recall skills for negative relative to positive and neutral pictures, individuals with ASD recalled the neutral pictures as well as the emotional ones. Findings of this study thus point to reduced influence of emotion on memory processes in ASD than in typically developing individuals, possibly owing to amygdala dysfunctions.”

C. Deruelle et al., Negative emotion does not enhance recall skills in adults with autistic spectrum disorders. *Autism Research* 1(2), 91–96, 2008

# Experimental evidence: molecular

What type of problems with neurons create these types of effects?

- Neural self-regulation mechanisms lead to fatigue or accommodation of neurons through leaky  $K^+$  channels opened by high  $Ca^{++}$  concentration, or longer acting GABA-B inhibitory synaptic channel.
- This leads to inhibition of neurons that require stronger activation to fire.
- Neurons accommodate or fatigue and become less and less active for the same amount of excitatory input.

Dysregulated calcium signaling, mainly through voltage-gated calcium channels (VGCC) is the central molecular event that leads to pathologies of autism.

<http://www.autismcalciumchannelopathy.com/>

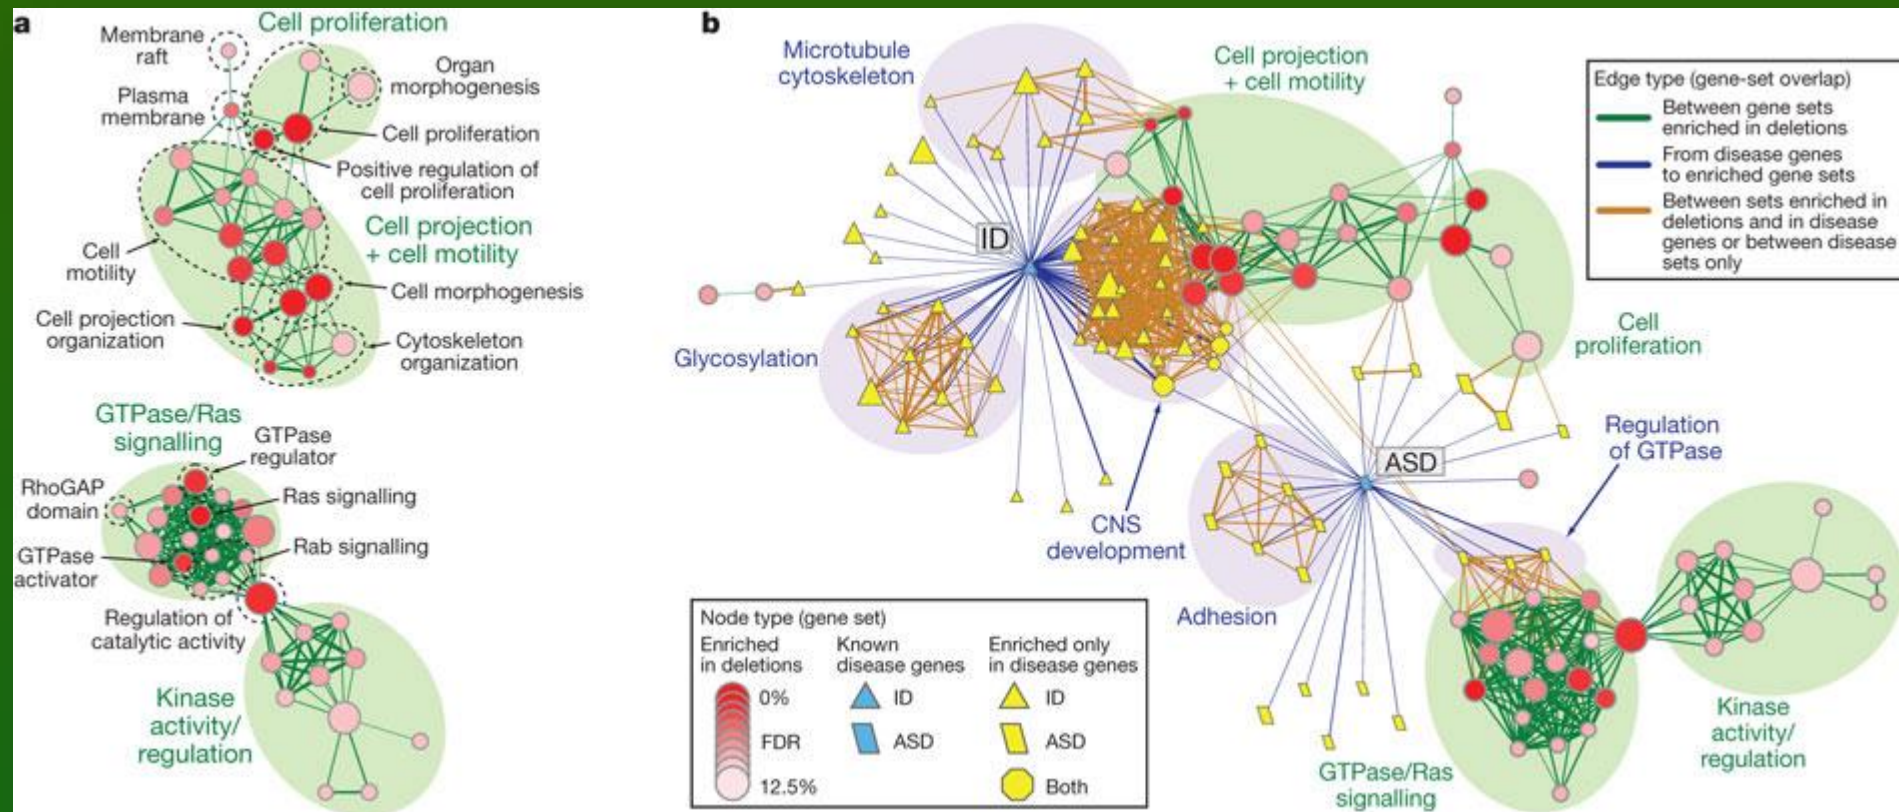

Calcium homeostasis in critical stages of development may be perturbed by genetic polymorphism related to immune function and inflammatory reactions and environmental influences (perinatal hypoxia, infectious agents, toxins).

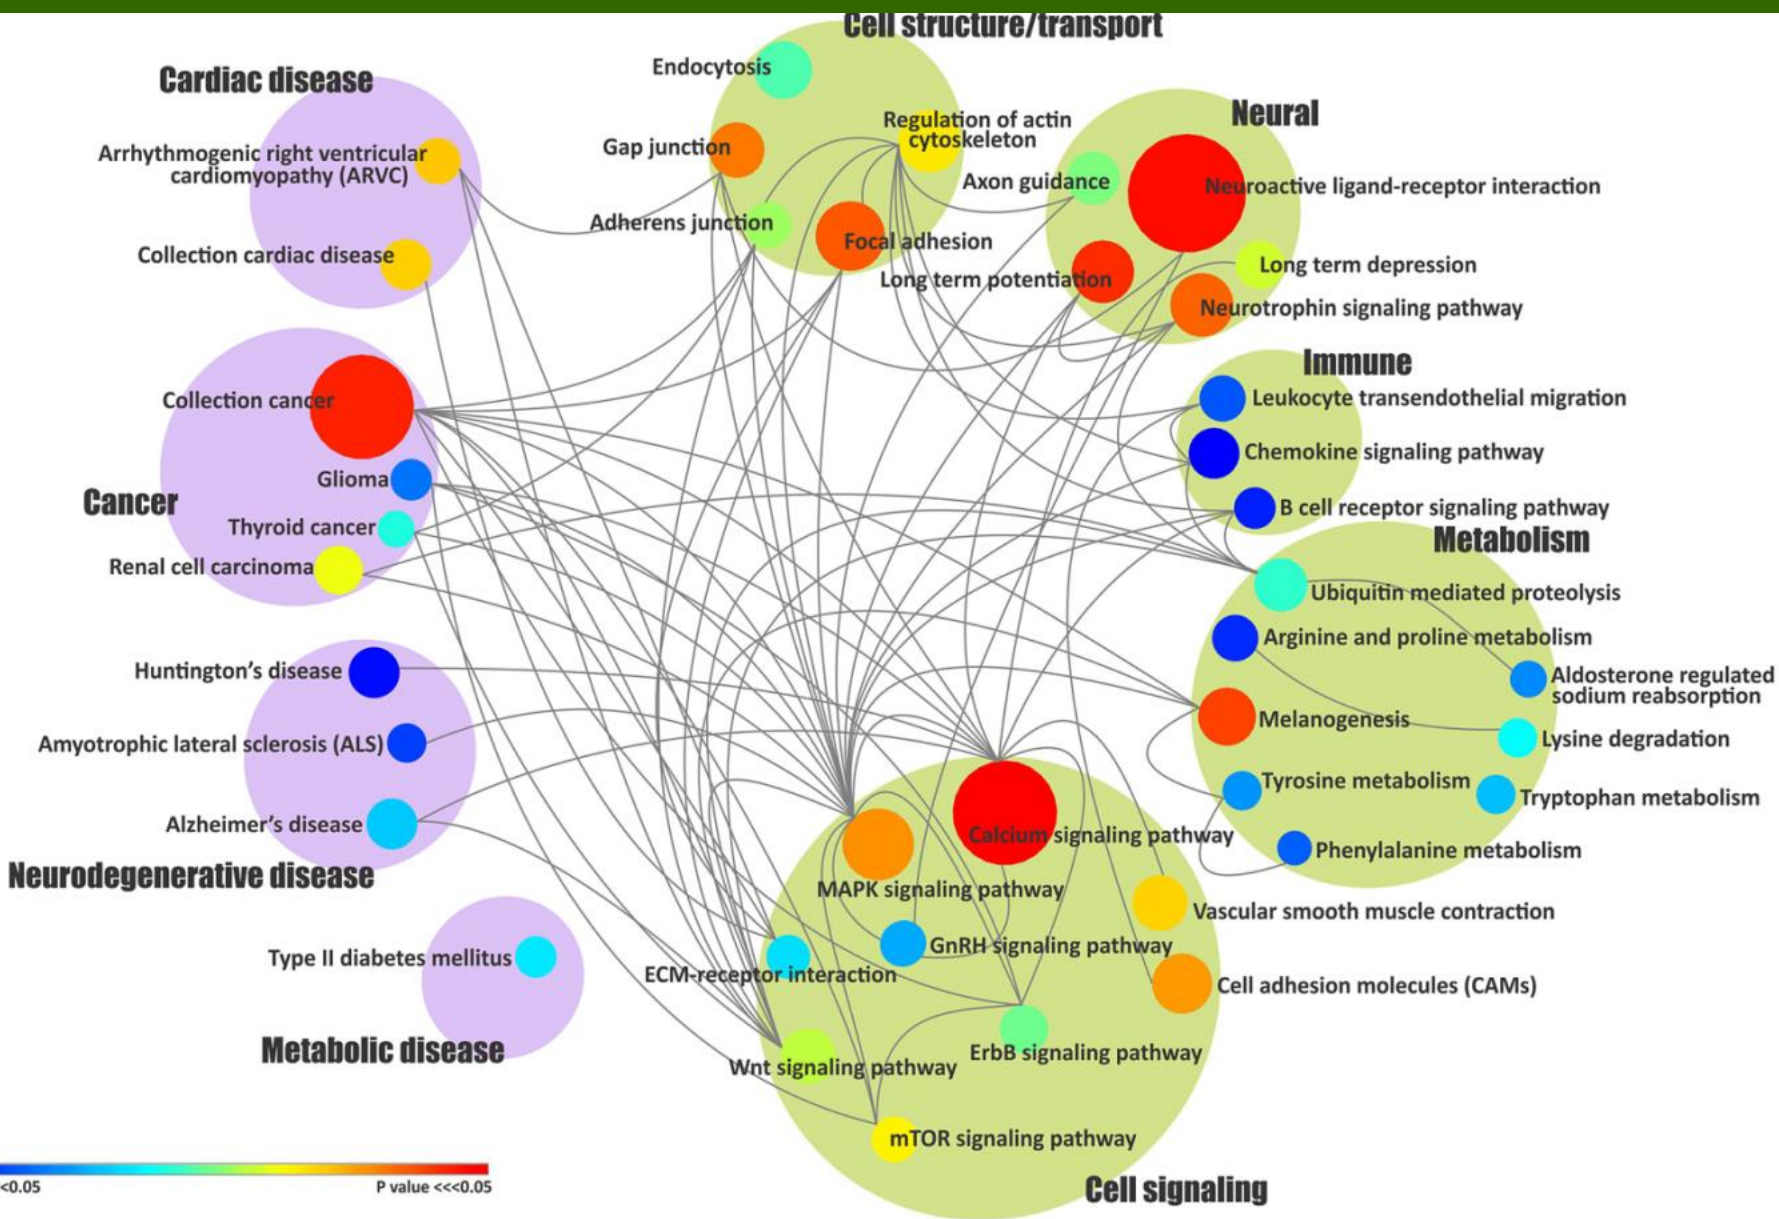

Genetic mutations => proteins building incorrect potassium channels (CASPR2 gene) and sodium channels (SCN2A gene).

# Genes & functions

Pinto, D. + 180 coauthors ... (2010). Functional impact of global rare copy number variation in autism spectrum disorders. Nature 466(7304):368-72  
[SFARI Human Gene Module](#) database in 5/2017 listed 881 ASD genes.

# Comorbidity

Many diseases are observed together with ASD symptoms.

Most frequent are:

- Hearing problems,
- Epilepsy, migraines,
- Various mental problems,
- Metabolic and digestion,
- Various allergies, skin, food, asthma
- ADHD?

Dysfunction of neurons but also of other types of cells due to the low-level molecular mechanisms that influence metabolic and neural processes.

# EEG 3 month old

Bosl, W. J., Tager-Flusberg, H., & Nelson, C. A. (2018). EEG Analytics for Early Detection of Autism Spectrum Disorder: A data-driven approach. *Scientific Reports*, 8(1), 6828.

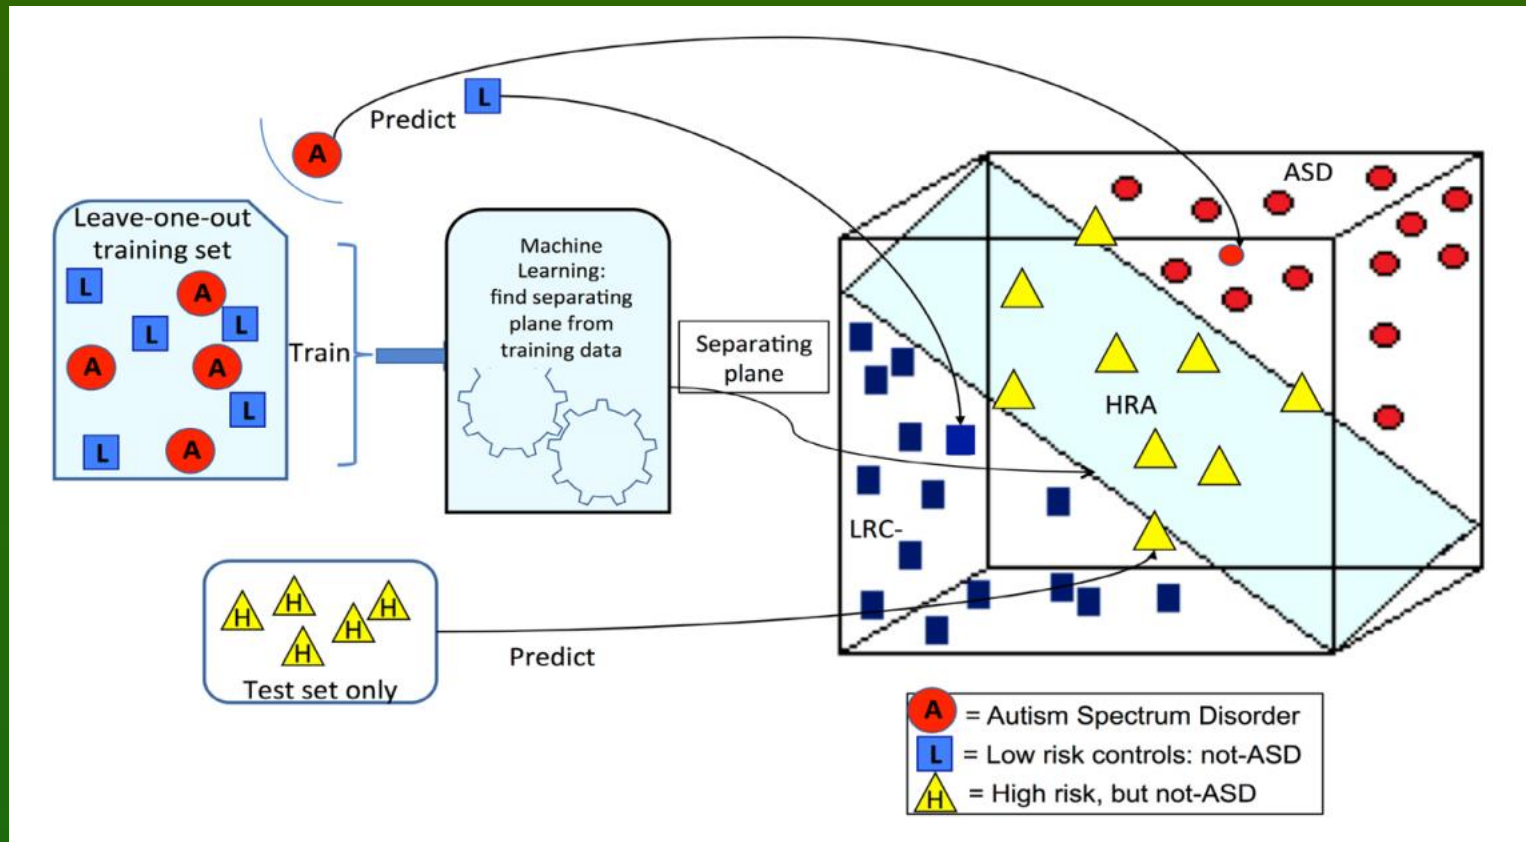

19 electrodes selected, 3-36 month old, ~ 95% success ...

**Features:** Nonlinear invariant measures of a time series and their physical interpretation, recurrence quantification analysis (RQA).

1. Sample Entropy (SampE)
2. Detrended Fluctuation Analysis (DFA), statistical self-affinity of a signal.
3. Entropy derived from recurrence plot (L\_entr)
4. Max. line length (L\_max), largest Lyapunov exponent
5. Mean line length (L\_mean), mean prediction time of the signal
6. Recurrence rate (RR), probability of recurrence
7. Determinism (DET), repeating patterns in the system
8. Laminarity (LAM), frequency of transitions between states
9. Trapping time (TT), time in a given state

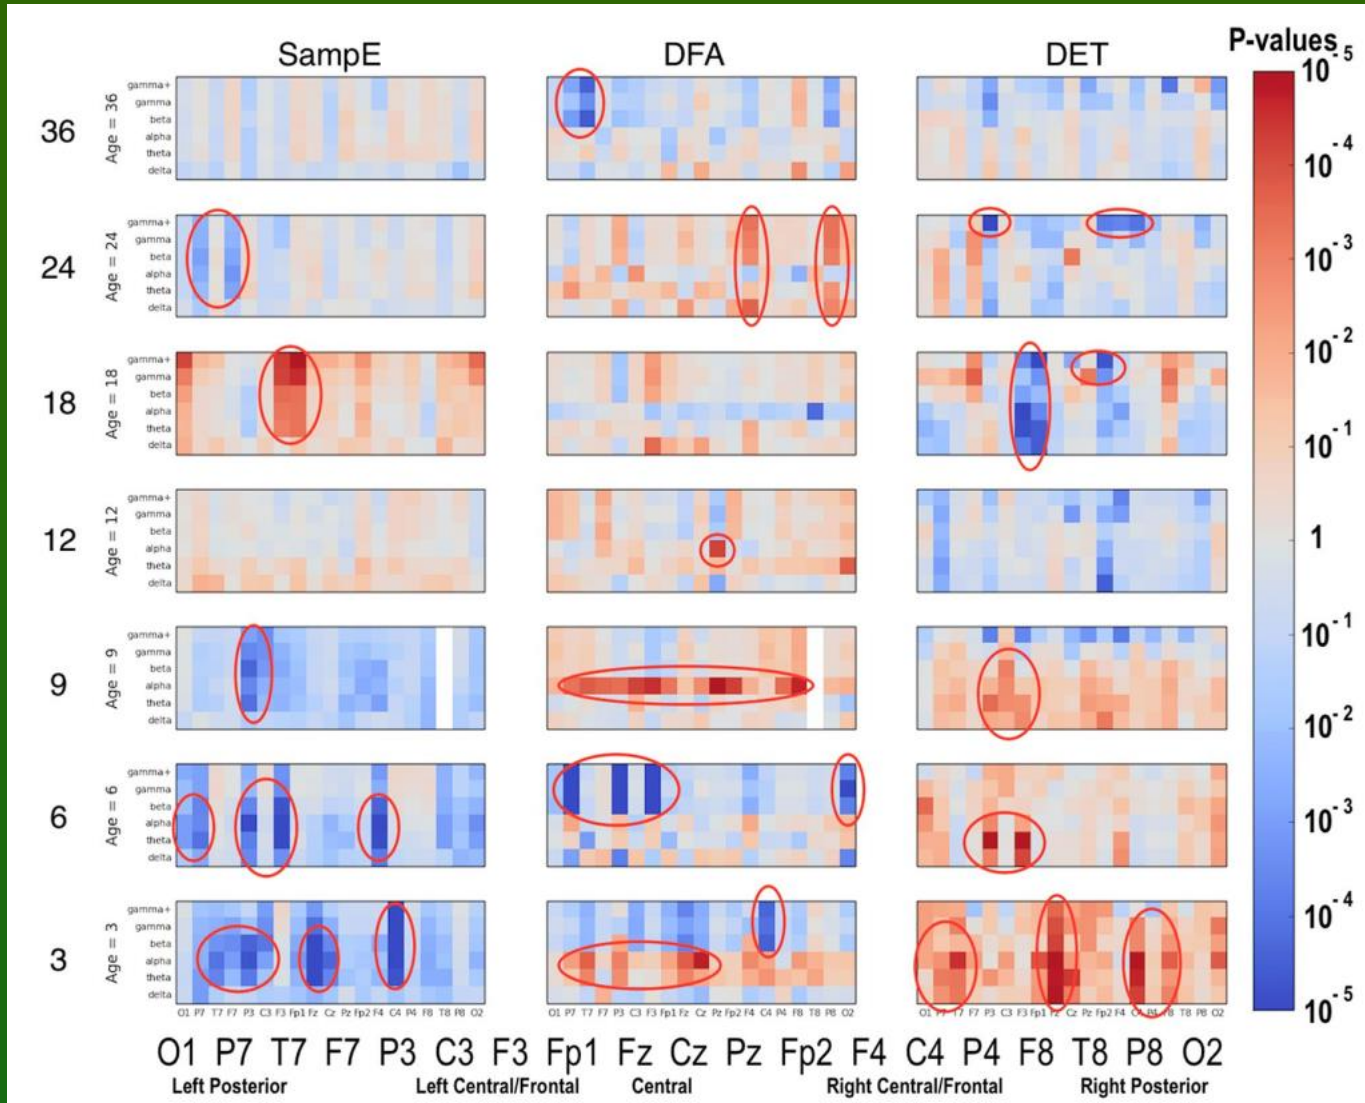

# ASD EEG SVM Classification

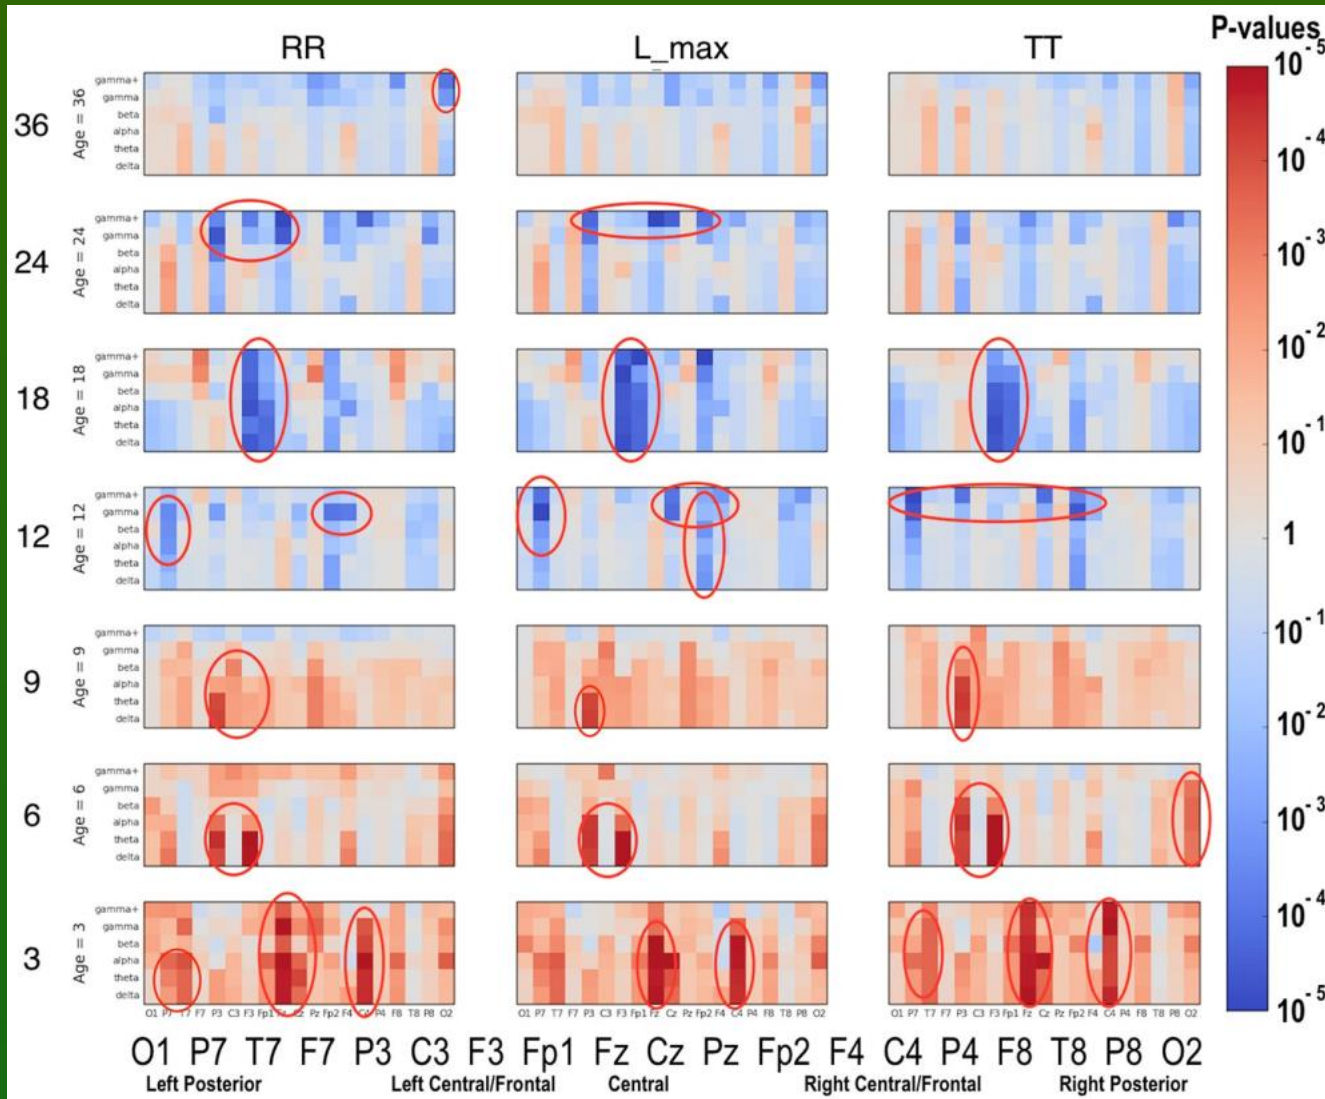

eegtools (for reading edf files): <https://github.com/breuderink/eegtools>  
pywavelets (for wavelet decomposition): <https://pywavelets.readthedocs.io>  
pyrqa (RQA calculations): <https://pypi.python.org/pypi/PyRQA/>  
nolds (Sample entropy and DFA calculations):  
scikit-learn (feature ranking and machine learning).

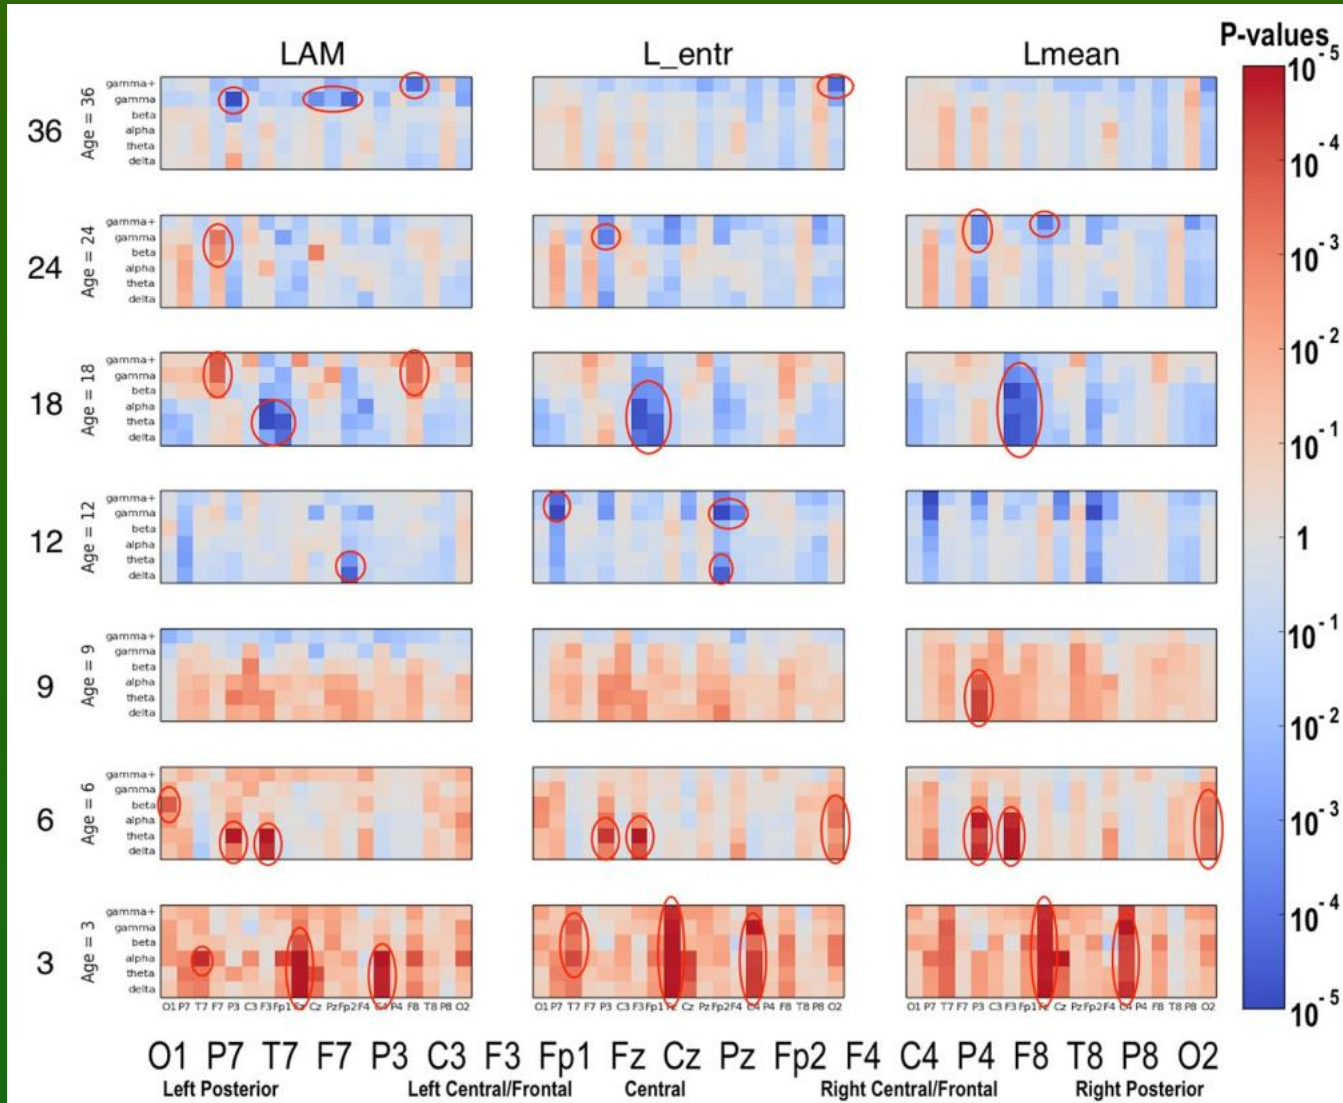

# ASD EEG Features

# ASD EEG Features

# ASD EEG Features

# ASD EEG SVM Classification

Developmental trajectories for SampE in the left temporal region (T7 sensor) in higher frequencies (beta+gamma) for ASD, LRC-, and HRA-

LRC low risk controls  
HRA high risk for ASD  
- no ASD

# ASD EEG SVM Classification

Developmental trajectories for DET in the entire frontal region (Fp1 + F7 + Fz + F8 + Fp2 sensors) in higher frequencies (beta + gamma) for ASD, LRC-, and HRA-.

# Questions/Ideas

Neurodynamics is a new useful language to speak about mental processes.

There are many parameters characterizing biophysical properties of neurons and their connections within different layers that control behavior.

- How does depth/size of basins of attractors depend on these parameters?
- How to measure and/or visualize attractors?
- How do attractors depend on the dynamics of neuron accommodation?  
Noise? Inhibition strength, local excitations, long-distance synchronization?
- Stability of more detailed neural models, real effects or artifacts?
- How will symptoms differ depending on specific brain areas?  
For example, *mu* suppression may be due to deep attractors ...
- What are precise relations to ion channels and proteins that build them?
- How can they be changed by pharmacological interventions?

# Smell: key marker?

How to find which ion channels are dysfunctional?

Loss of pain and smell reception: mutation of gene SCN9A, encoding the voltage-gated sodium channel Na(v)1.7 (J. Weiss, Nature 2011).

Autism: overspecific memory for images, words, numbers, facts, movements, except for impaired memory for olfaction, because many types of neural receptors important in olfaction are dysfunctional in ASD and ADHD?

# More questions/ideas

- How learning procedures may influence formation of basins of attractors? For example, learning to read may depend on the variability of fonts, handwriting may be much more difficult etc.
- Slow broadening of attractor basins?
- Spontaneous thoughts, local energy with low neural accommodation?
- Can one draw useful suggestions how to compensate for such deficits?
- Spatial attention shifts in Posner experiments – resonances depending on the timing, masking effects, flickering with different frequencies?
- Precise diagnostics, what type of problems at genetic/molecular level?
- Compensation effects: what changes in the network will lead to faster attention shifts?
- Will it help in diagnostics/therapy? Neurofeedback?  
We need to finish computational simulations and then do real test of some predictions.
